Approximate set membership data structures

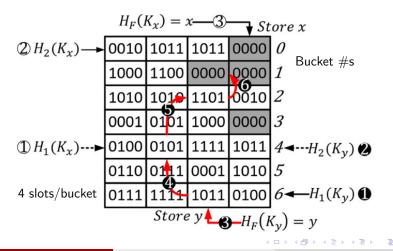

Examples: Bloom filters, Cuckoo filters [3], Morton filters [1, 2]...

VV	illiam	(Jian

・ロト ・ 同 ト ・ ヨ ト ・ ヨ ト

Cuckoo filters

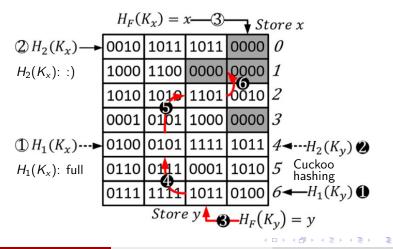

Fingerprints are fixed-width hashes of keys using H_F Buckets are determined by either H_1 or H_2

Cuckoo filters: insertions

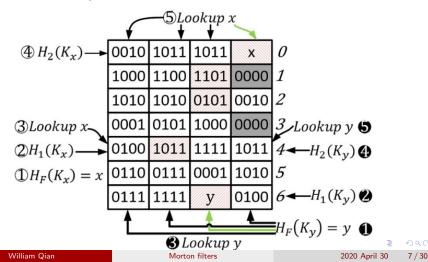

Pick empty slot in either bucket

No available slots: evict an entry and cascade via Cuckoo hashing

Cuckoo filters: lookups

Look in both buckets for matching fingerprint Found match: likely in set; no match: not in set

Morton filters: overview

Morton filters (MFs) [1, 2] are like Cuckoo filters (CFs), but MFs:

- Bias toward one hash function over the other
- Use a compressed block store
- Require 2x buckets, instead of 2^x buckets

→ Ξ →

Morton filters: primacy

Preferentially hash using H_1 ; H_2 is the backup

• Lookups generally require only one hash (and thus, cache line)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Morton filters: compressed block store

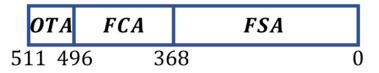

Fig. 3 A sample block in an MF that is performance-optimized for 512-bit cache lines. The block has a 46-slot FSA with 8-bit fingerprints, a 64-slot FCA with 2-bit fullness counters (64 3-slot buckets), and a 16-bit OTA with a bit per slot

- Sparseness \implies not all slots will be used
- Bitmaps to maintain meta information
- FSA: fingerprint storage array. Contains fixed-width fingerprints.
- FCA: fullness counter array. b bits/counter, $2^b 1$ slots/bucket.
- OTA: overflow tracking array. 1 indicates block/bucket overflow.

Morton filters: compressed block store

Block overflows occur when the FSA has run out of space

• Evicts some (any) fingerprint

Bucket overflows occur when the bucket's FCA has reached its max

• Evicts a fingerprint in the bucket

When a bucket's OTA bit is set, it indicates that if a key hashed there with H_1 isn't found in the bucket, we should look at its H_2 bucket as well.

Morton filters: compressed block store

Fig. 4 An MF's Block Store and a sample block's compressed format and logical interpretation, with corresponding buckets labeled 0 to 5. The FCA and FSA state dictates the logical interpretation of the block. Buckets and fingerprints are ordered right to left to be consistent with logical shift operations

offset() is always odd, and n is always even:

$$\begin{aligned} H_2(K)\&1 &= bucket(H_1(K) + (-1)^{H_1(K)\&1} \cdot offset(H_{fp}(K)), n)\&1 \\ &= (H_1(K) + (-1)^{H_1(K)\&1} \cdot offset(H_{fp}(K)))\&1 \\ &= (H_1(K)\&1) \wedge ((-1)^{H_1(K)\&1} \cdot offset(H_{fp}(K))\&1) \\ &= (H_1(K)\&1) \wedge ((-1)^{H_1(K)\&1}\&1) \\ &= (H_1(K)\&1) \wedge 1 \\ &= \sim (H_1(K)\&1) \end{aligned}$$

< □ > < 同 > < 回 > < 回 > < 回 >

 $H'(H_2(K), H_{fp}(K)) = bucket(H_2(K) + (-1)^{H_2(K)\&1} \cdot offset(H_{fp}(K)), n)$ =bucket($H_2(K) + (-1)^{(H_1(K) \& 1)+1} \cdot offset(H_{fn}(K)), n)$ $= bucket(H_2(K) - (-1)^{H_1(K)\&1} \cdot offset(H_{fp}(K)), n)$ =bucket($H_1(K)$ + $(-1)^{H_1(K)\&1}$ · offset($H_{fp}(K)$) $(-1)^{H_1(K)\&1} \cdot offset(H_{fn}(K)), n)$ =bucket($H_1(K), n$) $=H_1(K)$

< □ > < □ > < □ > < □ > < □ > < □ >

$H'(H_2(K), H_{fp}(K)) = H_1(K); H'(H_1(K), H_{fp}(K)) = H_2(K)$

 \therefore applying H' to an already-inserted key swaps its bucket.

< □ > < 同 > < 回 > < 回 > < 回 >

Morton filters: other features

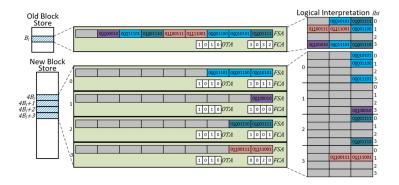

Block full array (BFA) is another bit vector that stores information about which blocks are full

- Insertions can query the BFA to avoid cascading evictions
- Extra overhead for deletes
- Only useful at high loads (FSA generally quite full)

.

Morton filters: other features

Resizing: MFs can only be resized by powers of 2

 Use significant bits of the fingerprint to assign keys to child buckets

< □ > < □ > < □ > < □ > < □ >

Environment

- AMD Ryzen Threadripper 1950X
 - 2 sockets, 8 cores each, hyperthread enabled
- 512-bit blocks
 - 3-slot: 16-bit OTA, 128-bit (64 imes 2) FCA, 46-slot FSA, 8-bit fp
 - 7-slot: 17-bit OTA, 63-bit (21 imes 3) FCA, 54-slot FSA, 8-bit fp
 - 15-slot: 17-bit OTA, 63-bit (21 imes 3) FCA, 54-slot FSA, 8-bit fp
- Benchmarks: MF (this work), CF (12 bits)

< □ > < □ > < □ > < □ > < □ > < □ >

Error rate

Error rate roughly matches projected error rates

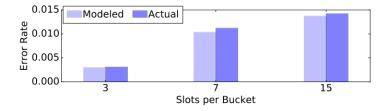

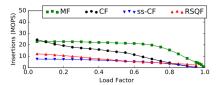

Fig. 11 The MF implementation's false positive rate closely matches Eq. 5. All MFs have a block load factor of 0.95. The MF with 3-slot buckets uses 128 bits for its FCA versus the 7- and 15-slot that use 63 and 64 bits, respectively

	liam	

→ Ξ →

Throughput

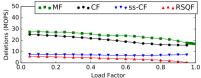

Fig. 14 An MF's insertion throughput is $0.94 \times$ to $20.8 \times$ that of a CF

Fig. 16 An MF's deletion throughput is $1.1 \times \text{to } 1.3 \times \text{higher than that}$ of a CF

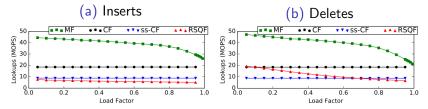

Fig. 12 An MF's positive lookup throughput is about $1.6\times$ to $2.4\times$ higher than a CF's

Fig. 13 An MF's negative lookup throughput is about $1.3\times$ to $2.5\times$ higher than a CF's

(d) Negative lookups

2020 April 30 24 / 30

Throughput (Intel)

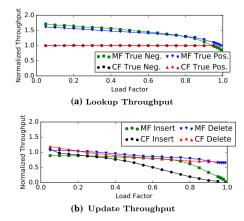

Fig.26 On a Skylake-X server, MF lookup throughput is on par with to nearly $1.8 \times$ higher than a CF's. MF deletion throughput is about $0.90 \times$ to $1.1 \times$ a CF's. MF insertion throughput is $0.82 \times$ to $4.8 \times$ that of a CF. Results are normalized to a CF's lookup throughput on a Skylake-X CPU

Block full array

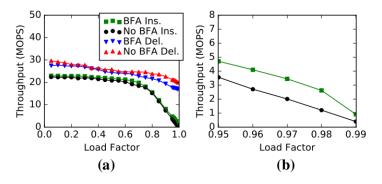

Fig. 21 MF insertion and deletion throughput with and without the BFA enabled. \mathbf{b} zooms in on the lower right corner of (\mathbf{a})

2020 April 30 26 / 30

Takeaways

- Spatial underutilization is expensive!
- This is an interesting metadata design
- Biasing toward one hash function reduces cache costs
- Parity tricks are really cool :)
- Morton filters are competitive with cuckoo filters, and more memory efficient

→ Ξ →

Discussion

- Is NUMA important here? How might a NUMA-aware implementation work?
- What concurrency overheads might exist with this solution?
- This is published in VLDB(J), which ostensibly means it should be somewhat database-related. What are some implementations/optimizations that might be useful if we wanted to implement this in a distributed memory model?

.
